The Low-Mass Outflow Phenomenon

Bachiller et al. (2001), Looney et al. (2007), Neufeld et al. (2009)

Three physical components
High-velocity wind
Shock
Bipolar outflow cavity

Specific outflow shock chemistry

→ Evidence for grain mantle/core sputtering and dust shattering: CH₃OH/SiO
→ high-temperature gas phase reactions: HCN

Previous results and questions

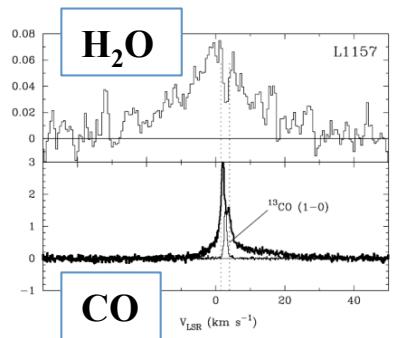

Shock Models predict a strong water enrichment in outflow shocks

(Neufeld & Kaufman 1996; Flower & Pineau des Forets 2010)

H₂O thermal line emission is a selective tracer of outflows

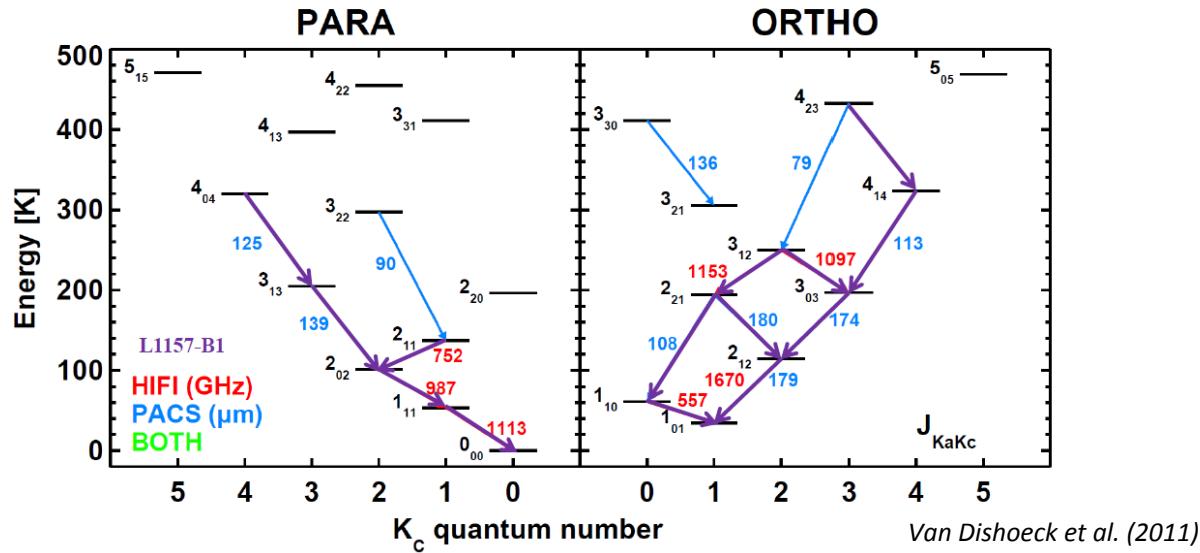

- ISO: water in *warm* outflow gas (Liseau 1996; Giannini, 2001)
- SWAS, *Odin*: *o-H₂O* 557 GHz
- First resolved line profiles: high-velocity *wings* (Franklin, 2008; Bjerkeli 2009)
- First estimates of X(H₂O) in outflow/shocks : 10⁻⁷ to 10⁻⁴

Angular resolution: several arcmin → only a global view on H₂O properties

Where is H₂O formed in outflows and by which processes: gas phase / dust grains ?
Which physical component(s) of the outflow are traced by H₂O ?
What is its role in the energy budget ?

The Promise of Herschel

Three assets to study outflow shocks:

Both HIFI and PACS observed H₂O lines probing a wide range of excitation

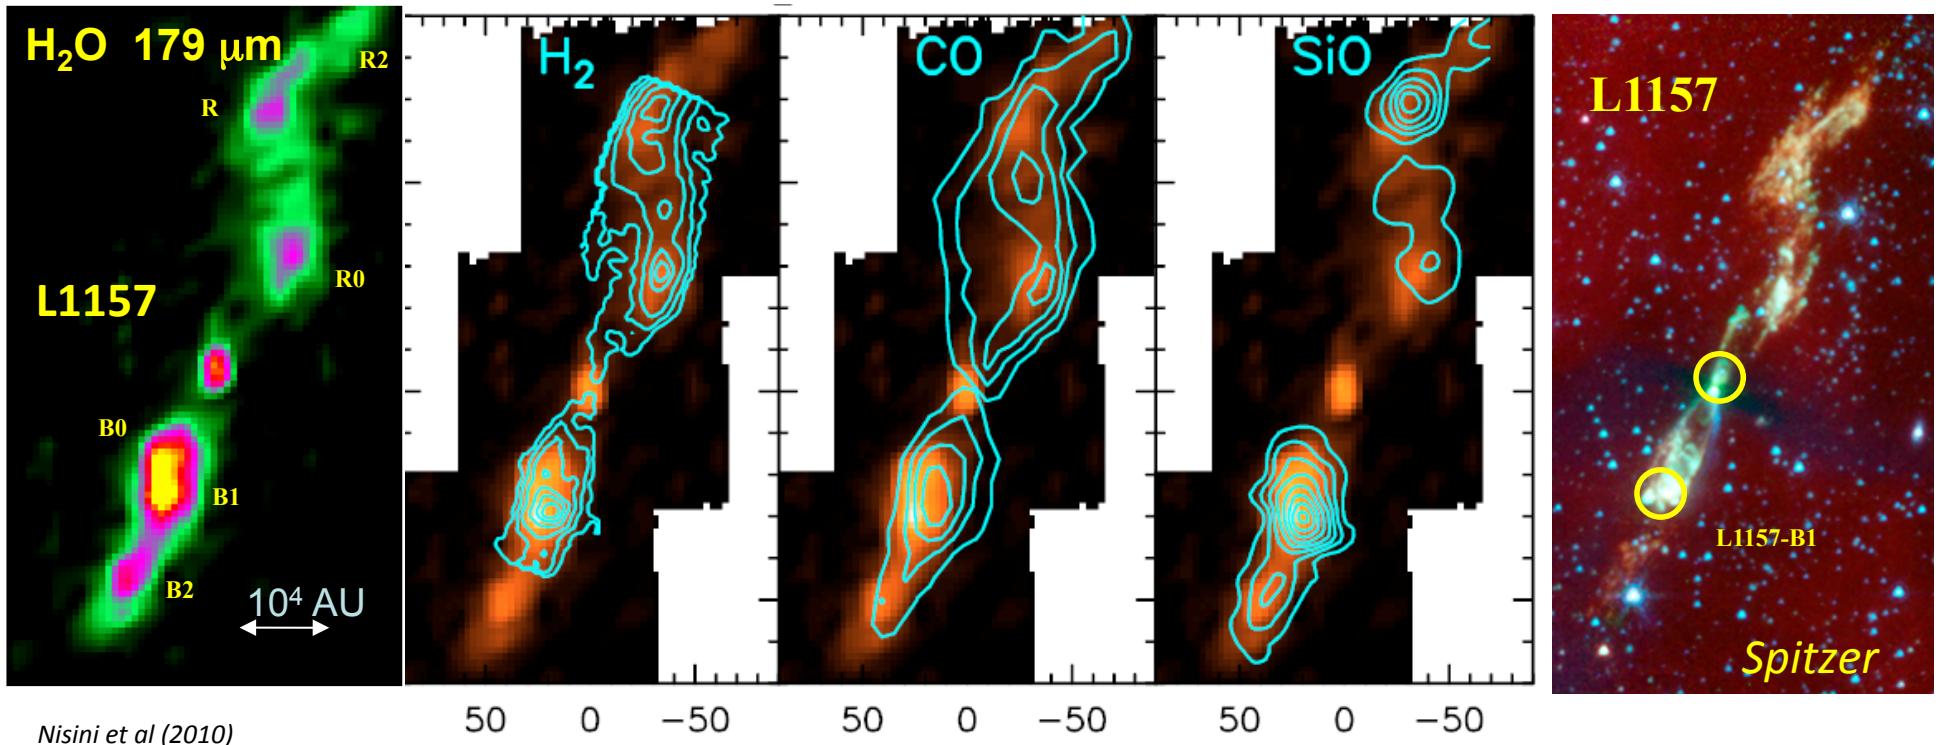

Angular resolution: 40'' – 6'' : comparable to ground based telescopes (IRAM, APEX)

Spectral resolution down to ~ 1 MHz (HIFI) : kinematics of low- and high-excitation gas

Water Emission in Outflows

Also : Bjerkeli et al. (2013), Nisini et al. (2013), Santangelo et al. (2014)

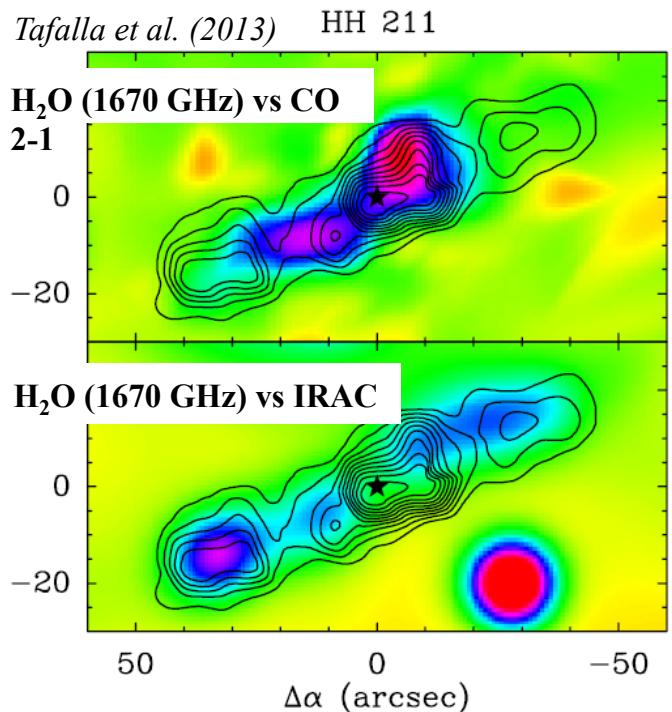

Strong water emission from the embedded protostar and the active shock regions B0-B2 and R0-R2 in the outflow.

H₂O peaks match the H₂ emission peaks (warm gas : 300K) , SiO (?), not with CO 2-1

+ ODIN/SWAS 557 GHz : H₂O from small size, water-rich clumps: X(H₂O) ~ 1(-4)

Outflow survey

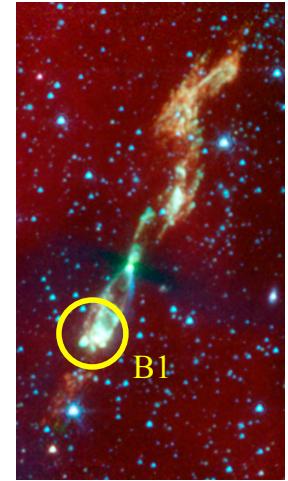

$$I^*[\text{IRAC4}] (\text{MJy sr}^{-1}) = 0.4 I[\text{H}_2\text{O}(1670)] (\text{K km s}^{-1}).$$

H₂O and the low-J CO lines trace different gas components
Close association between H₂O 557/1669 GHz and warm H₂ gas (300-500K)
Emission : narrow range excitation conditions

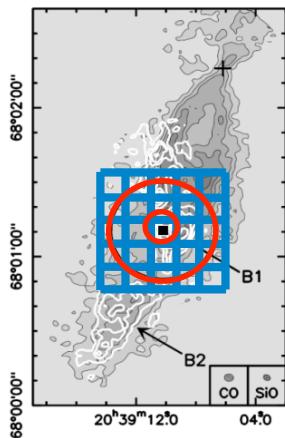

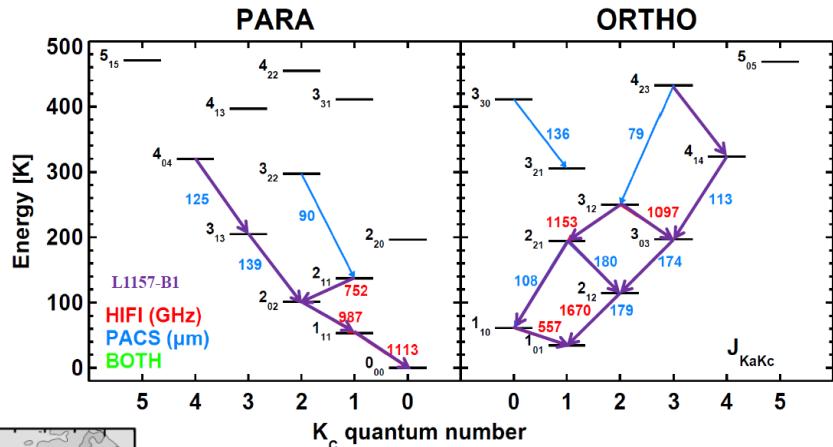

The outflow shock L1157-B1

Prototype for outflow shock studies
HIFI/PACS Line survey in CHESS (C. Ceccarelli et al. 2010)

→ Shock Physical and Chemical structure

Complementary data

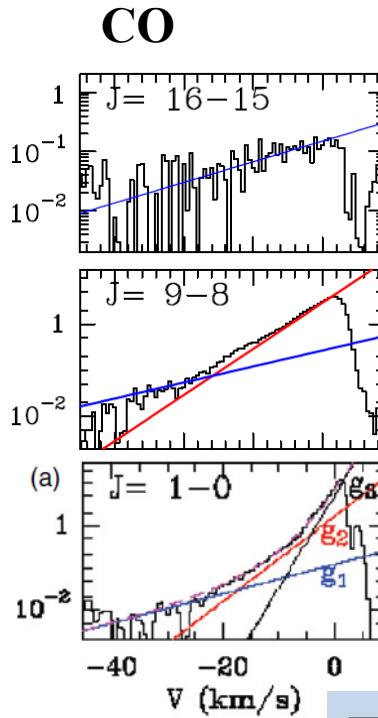

- IRAM 30m line survey of L1157-B1 : 80 – 350 GHz
- Sub/Millimeter line emission maps: IRAM 30m, PdBI, CSO
- IRAC Spitzer H₂ maps

The most complete water line set obtained for a shock
13 transitions : 9 HIFI , 7 PACS
9 ortho/5 para

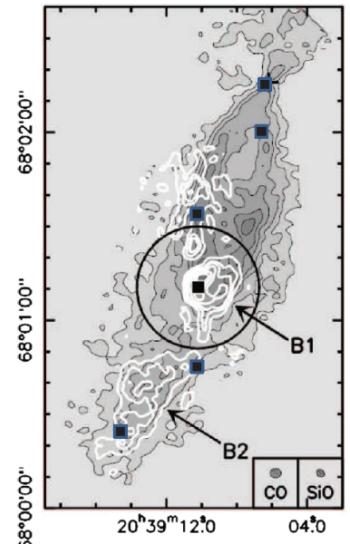

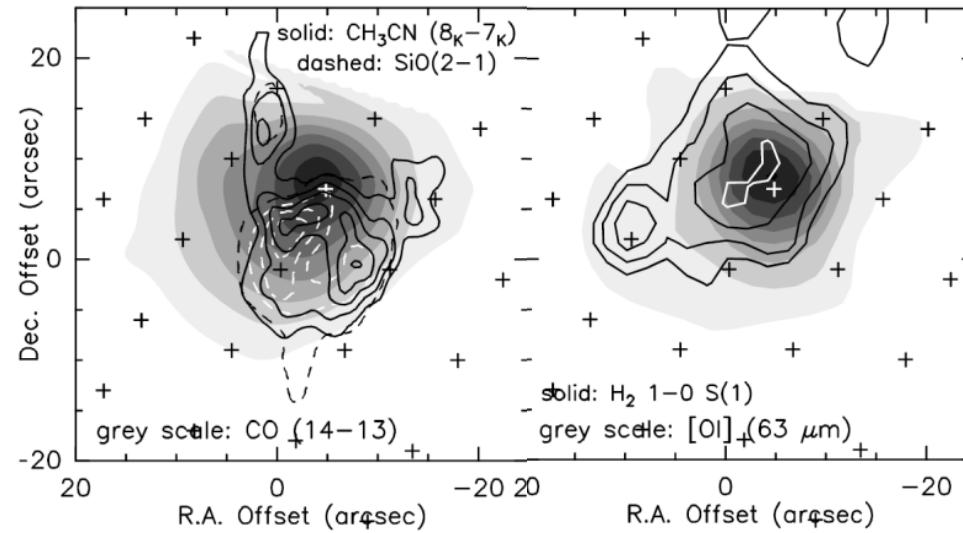

- + High-J CO, CS, HCN, ...
- + OH, NH₃, HDO

Physical Structure of L1157-B1

Lefloch et al. (2012)

Three shock components with specific spectral signatures: $T \propto \exp(v/v_0)$

Double Shock structure

- B1 outflow cavity walls
- the jet impact region against B1 cavity

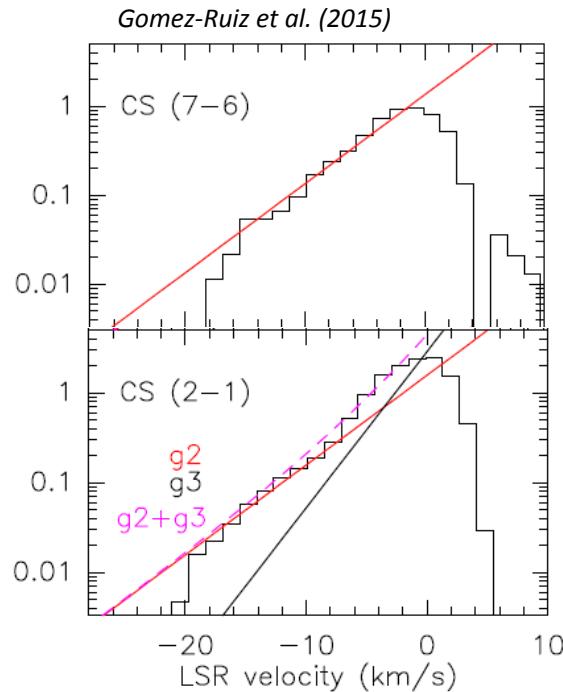

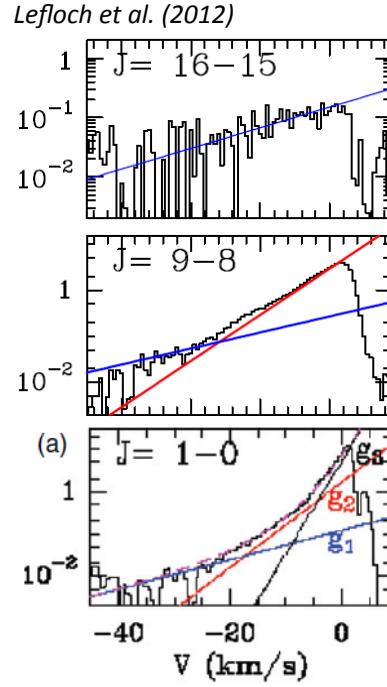

Cavity associated with previous ejection : B2

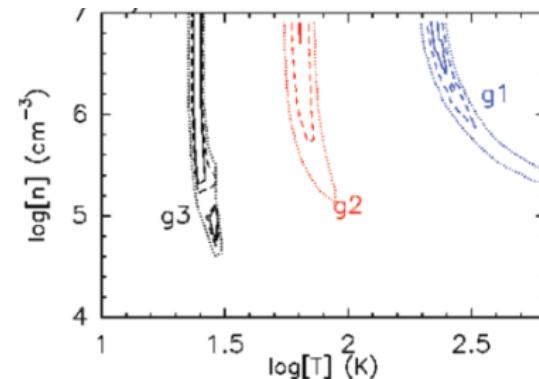

Physical Structure of L1157-B1

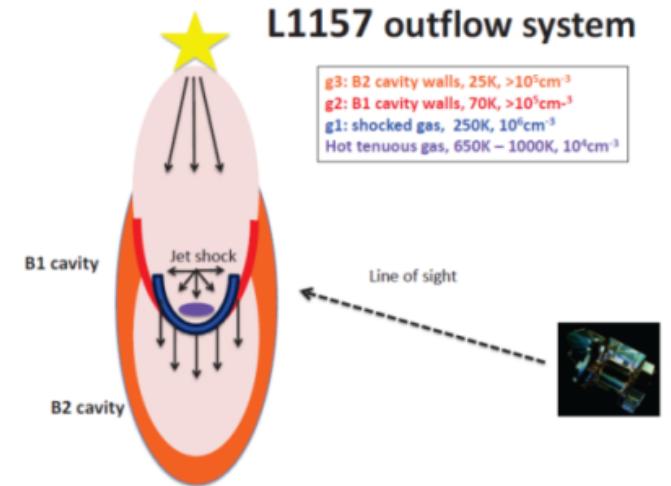

Three shock components with specific spectral signatures

Spectral signatures are essentially independent for a wide range of species

L1157 outflow system

**Physical conditions are homogeneous:
Isothermal, uniform density**

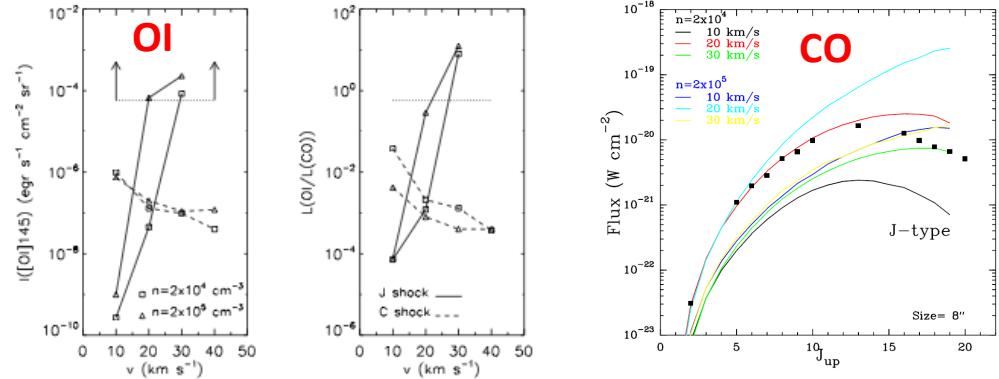

Physical Structure of L1157-B1

Jet Impact Shock region

Bright OI emission and CO are consistent with a J-type shock

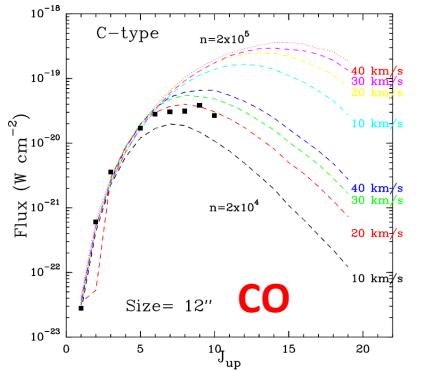

Flower & Pineau des Forets (2010)

$$n(H_2) = 10^4 \text{ cm}^{-3}$$

$$V_s = 20-30 \text{ km/s}$$

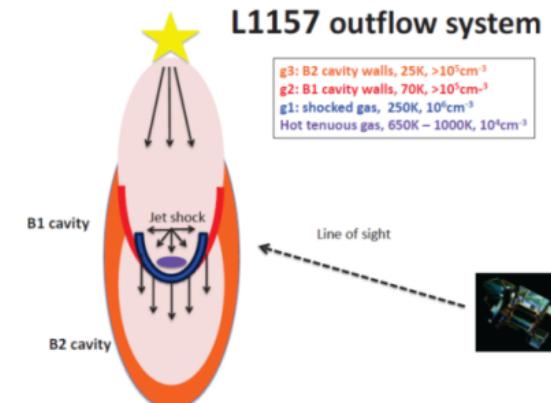

B1 Outflow cavity

Bright CO emission is consistent with a C-type shock

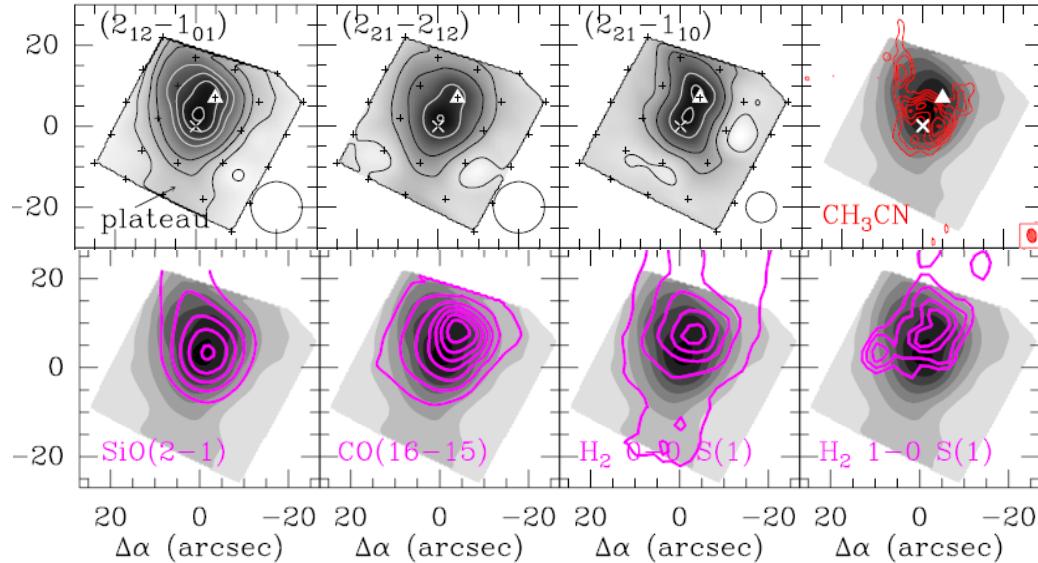

$$n(H_2) = 10^4 \text{ cm}^{-3}$$

$$V_s = 20 \text{ km/s}$$

Water Emission in L1157-B1

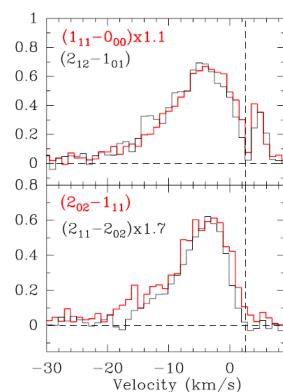

Bowshock

Emission detected over the bowshock

Emission peak shifted wrt high-excitation gas:

CO (16-15), H₂ 1-0 S(1)

Two contributions at apex and jet shock ?

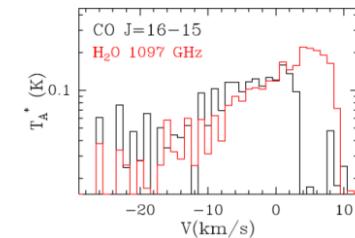

HIFI line profiles : Two physical components
1669, 1113, 557 GHz

987, 752 GHz

Comparison H₂O – CO line profiles

H₂O 1097 GHz / CO 16-15 does not vary with velocity

No evidence for X(H₂O) increase with velocity

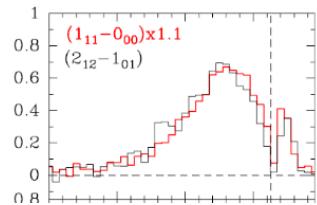

Water Emission in L1157-B1

The Two-Temperature model

1 – Warm, Dense Component

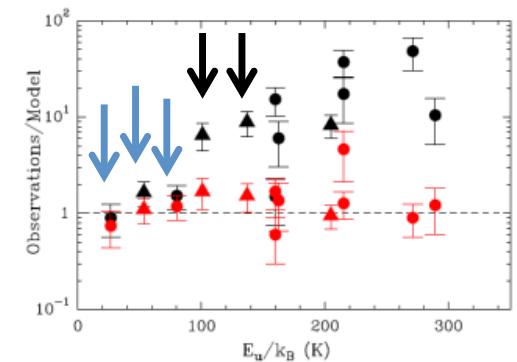

$T=250\text{K}$, $n(\text{H}_2)=2\times10^6 \text{ cm}^{-3}$, size= $10''$, $N(\text{o-H}_2\text{O})=2\times10^{14} \text{ cm}^{-2}$

→ best-fit for o/p $\text{H}_2=0.5$ (Spitzer: 0.6, *Nisini et al. 2010*)

→ best-fit for o/p $\text{H}_2\text{O}=3$

Warm Component Emission from the jet impact shock region

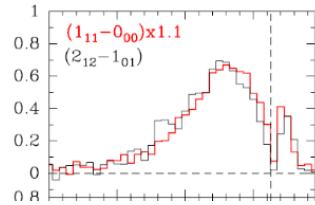

Water Emission in L1157-B1

The Two-Temperature model

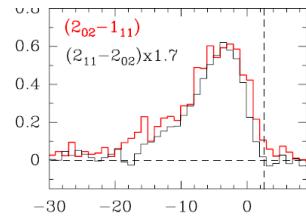

1 – Warm, Dense Component

$T=250\text{K}$, $n(\text{H}_2)=2\times10^6 \text{ cm}^{-3}$, size= $10''$, $N(\text{o-H}_2\text{O})=2\times10^{14} \text{ cm}^{-2}$
 → best-fit for o/p $\text{H}_2=0.5$ (Spitzer: 0.6, Nisini et al. 2010)
 → best-fit for o/p $\text{H}_2\text{O}=3$

Warm Component Emission from the jet impact shock region

2 – Hot, Diffuse Component

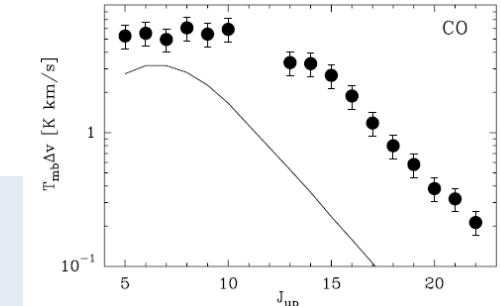

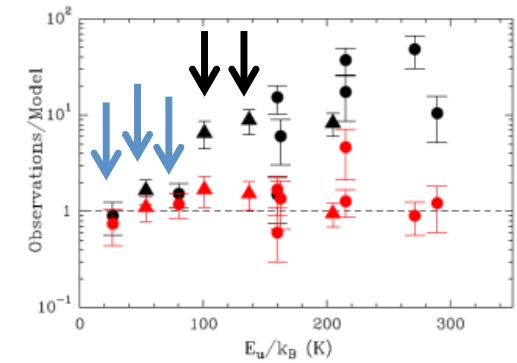

$T=1000\text{K}$, $n(\text{H}_2)=2\times10^4 \text{ cm}^{-3}$, size= $2.5''$
 $N(\text{o-H}_2\text{O})=9\times10^{16} \text{ cm}^{-2}$

Higher-T solutions for higher o/p H_2 ratio
 $T=1000\text{K}$, o/p- $\text{H}_2=3$ is consistent with Spitzer

This high-T component is not detected in the PACS CO lines

*Temperature distribution similar to that observed in H_2 with Spitzer:
 Stratification in the post-shock gas ?*

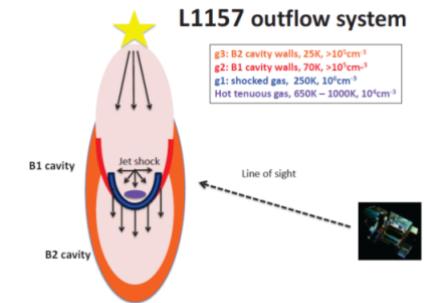

Water Abundance and Line Cooling

	Tk (K)	n(H ₂) (cm ⁻³)	X(H ₂ O)	Size (")	L(H ₂ O)	L(CO)
Warm	250-300	(1-3)(6)	(0.7-2.0)(-6)	10	0.002	0.004
Hot	900-1400	(0.8-2)(4)	(1.2-3.6)(-4)	2.5	0.03	0.01

$$L(OI) = 3 \times 10^{-3} L_o \quad L(OH) = 4 \times 10^{-4} L_o \quad L(H_2) \approx 0.03 L_o \quad (Nisini \text{ et al. 2010})$$

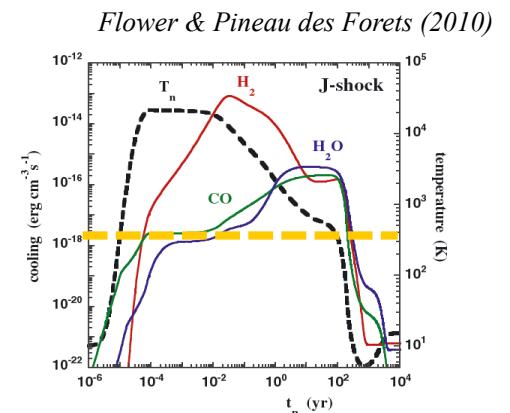

Warm component

Partly dissociative J-type shock : **Low X(H₂O) ~ 10⁻⁶**
 $L(CO) \sim L(OI) \sim L(H_2O)$

Similar results by Tafalla (2013); Bjerkeli et al. (2012)

Hot component

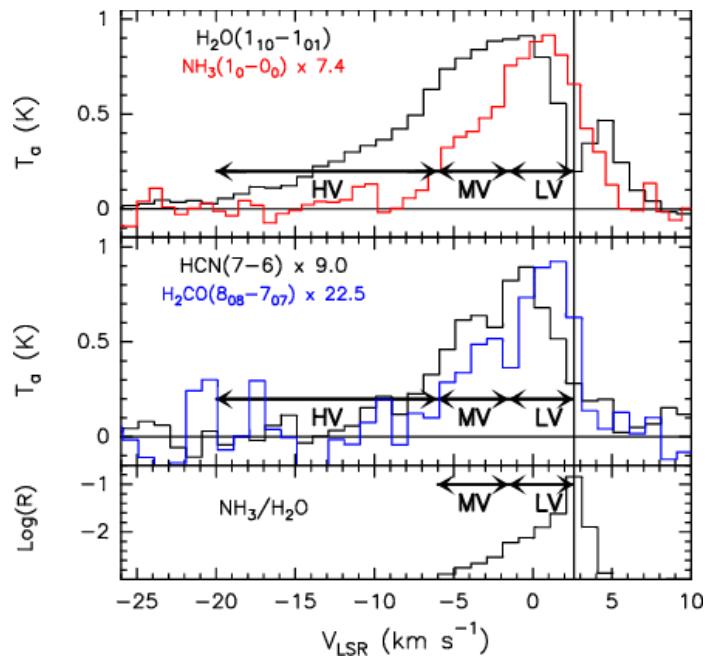

High X(H₂O) ~ 10⁻⁴ : C-type shock ? (Kaufman & Neufeld 1996)
 All O not locked up in CO is converted to H₂O
 $L(H_2O) \sim L(H_2) > L(CO)$

Deuterated formaldehyde is associated with shocked gas in the cavity walls and the arch
→ SPUTTERING

Extended Formaldehyde emission :
 Tip of bowshock → gas phase formation

D-fractionation : 0.04 (arch) to 0.15 (walls)
 D-fractionation on mantle grains in the arch: ~ 0.11

Conclusions

Herschel has allowed us to probe the structure of molecular shocks: double shock (jet, cavity). Shock models succeed approx. in accounting for their physical properties based on CO SLED.

H_2O 557/1669 GHz lines trace a warm (300-500K), dense gas component detected in H_2 with Spitzer and high-J CO (not low-J): very good correlation morphology and intensity.
Low water abundance ($X \sim 10^{-6}$) and physical properties are well accounted for by J-type shock components of small size.

Detailed shock studies share similar conclusions :

Modelling of the H_2O emission requires in general a multi-temperature distribution:

A second, compact component of hot (1000K) and less dense gas is required to account for H_2O SLED. This component may be detected (or not) in the high-J CO lines.

It dominates H_2O production in L1157-B1 shock region ($X \sim 10^{-4}$).

→ The exact physical relation between these components remains to be understood:
stratification in the post-shock region ?

$X(\text{NH}_3)/X(\text{H}_2\text{O})$ abundance is sensitive to T_{\max} in the shock and could be used to constrain the shock parameters.

HDO studies are a useful tool to determine the history of ice mantle formation in the cloud.

Thank You
