

# Bio-habitability and biotic abundance of Red Dwarf planets with future telescopes

51ESLAB, Noordwijk 7.12.2017

A. Wandel

Hebrew University of Jerusalem

# Habitable Zones of red dwarf stars

## Kepler-62 System

Planets and orbits to scale

ESLAB 51 2017 Wandel

Solar System

# Why M-dwarfs?

- **Abundant: 75% of all stars are M-dwarfs**
- **Easier bio-signature are detection**
- **Faint hosts → smaller habitable zones (HZ),**
- **Planets in the HZ are nearer host star**
- **→ Shorter periods – easier to detect (transit/RM)**
- **HZ planets are locked →**
- **wider surface temperature range (wandel 2017)**
- **a wider effective Habitable Zone**

# Why not M-dwarfs?

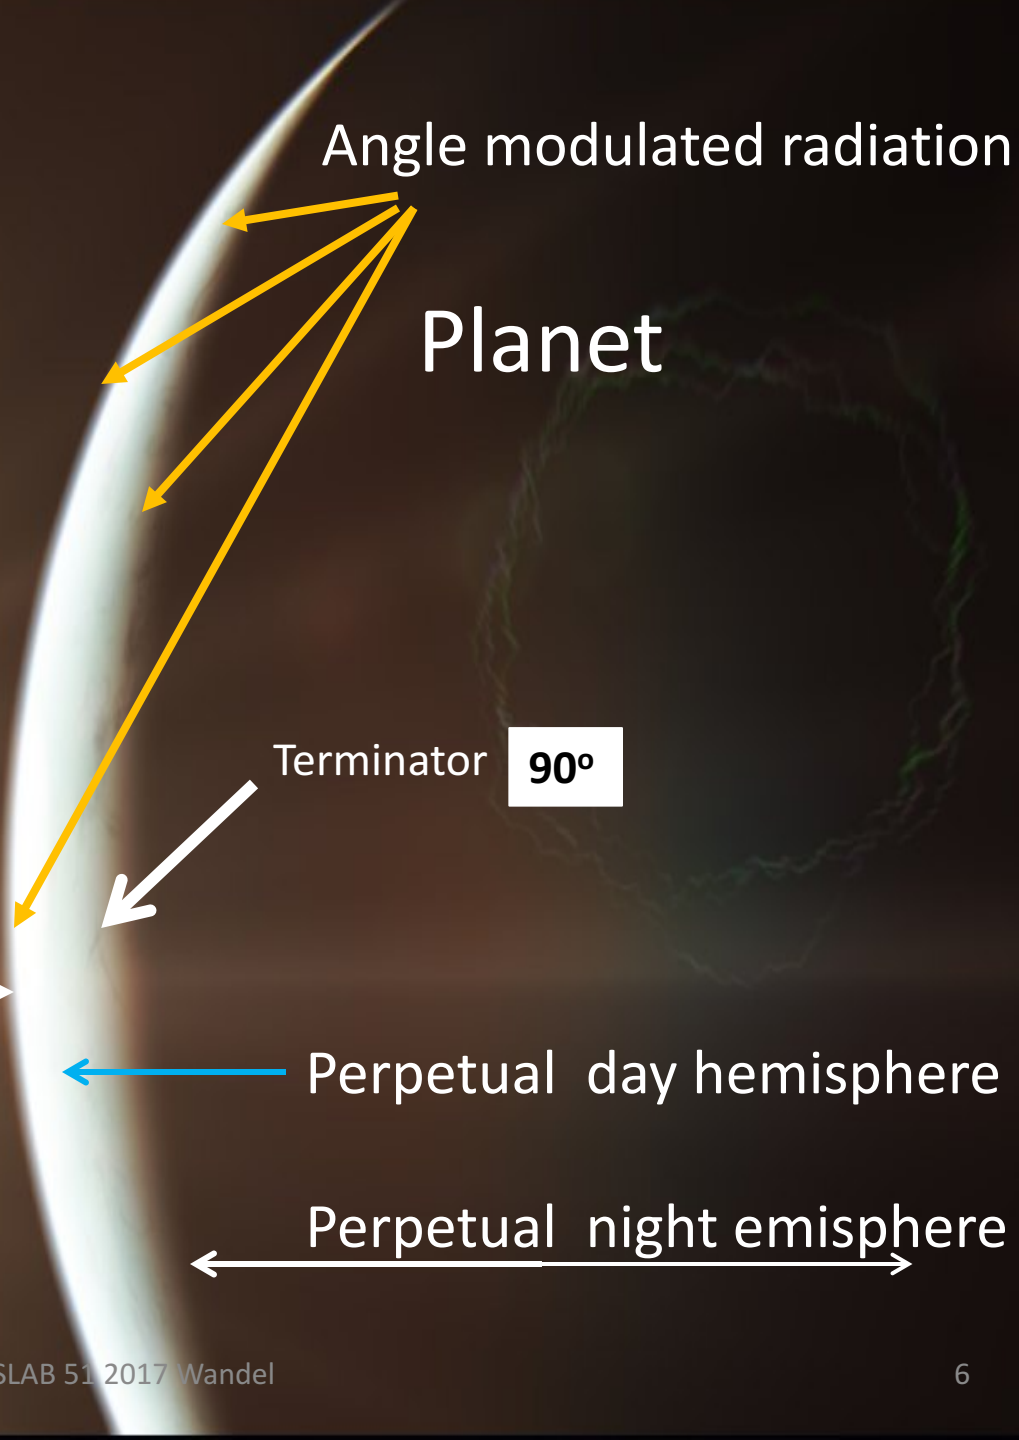

- Relatively stronger XUV flux for longer epoch
- **Energetic early stellar evolutionary stages**
- May erode the atmosphere
- May lead to loss of surface water
- **But: hydrosphere may be re-acquired (e.g. comets)**
- **HZ planets are locked** →
- **water may be trapped as snow on the night side (Leconte)**
- **Locked planets hostile to life as we know it? (but see Gale & Wandel 2017)**

Red Dwarf Star

Substellar point  
Latitude 0°

Angle modulated radiation

Planet

Terminator 90°

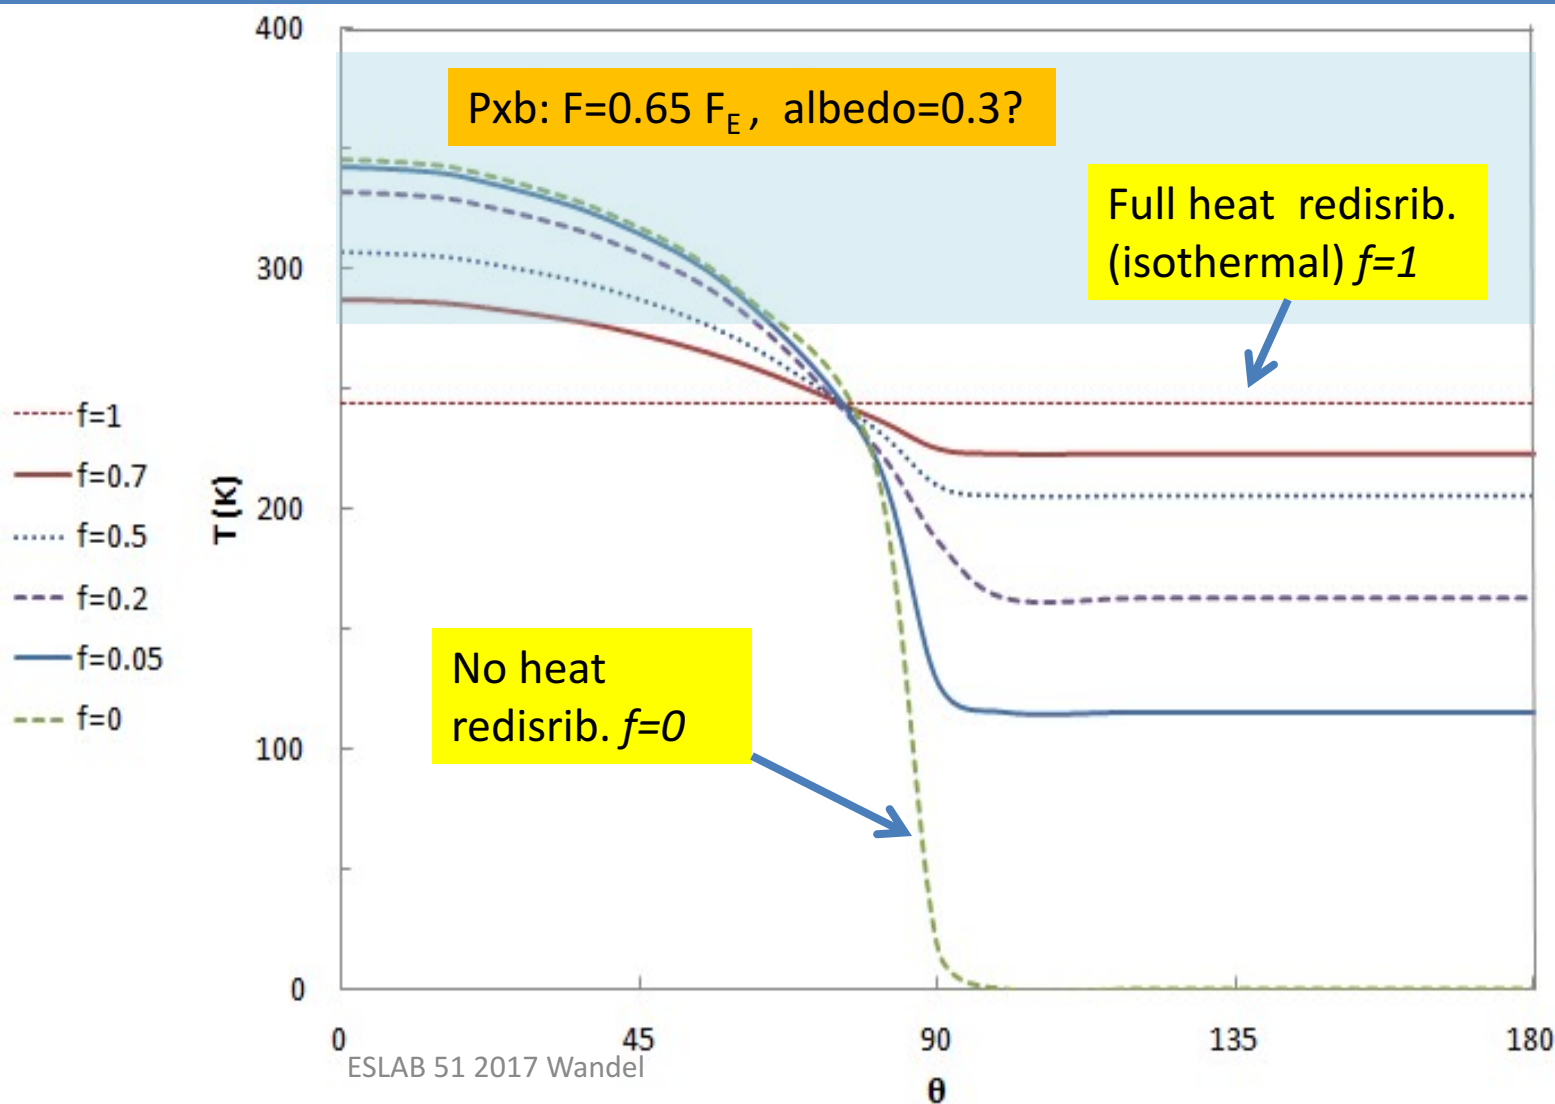

Perpetual day hemisphere

Perpetual night hemisphere

Not to scale

# Surface T vs. latitude model for Proxima b

$f$  - heat redistribution factor (global advection)

Wandel 2017

# We define the combined heating factor $A$

1. Sunlight arrives

**Stellar flux-  $F$**

2. Much of sunlight is reflected

**Albedo -  $a$**

Clouds

Atmosphere

6. Some infrared radiation "leaks" into space

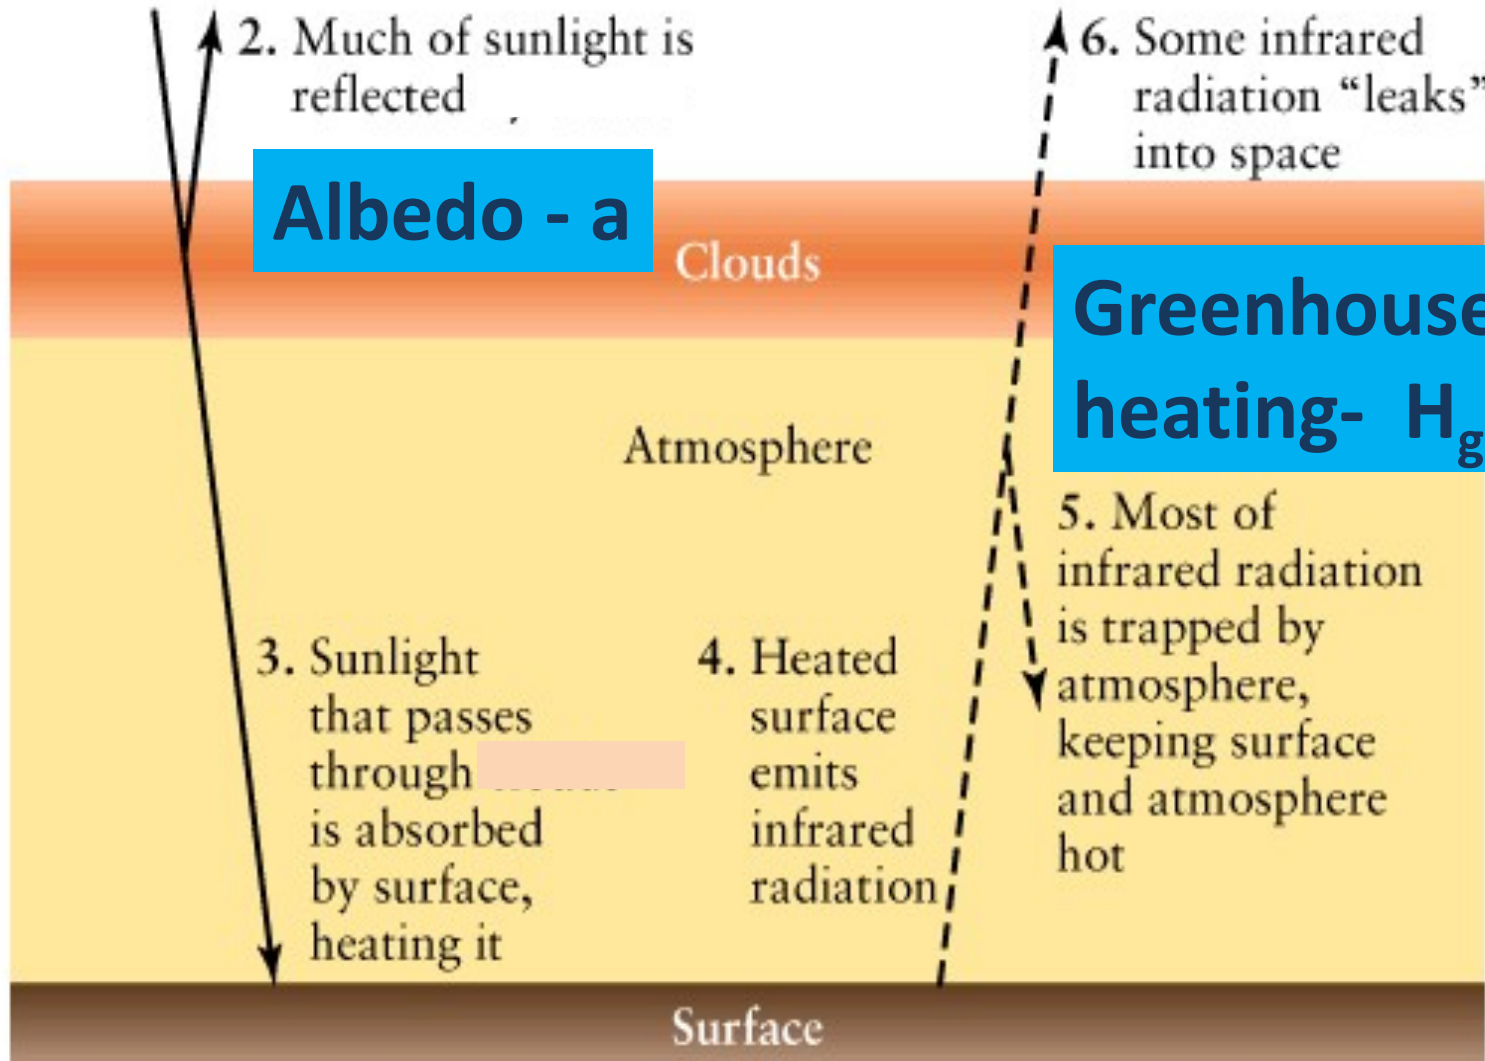

**Greenhouse-heating-  $H_{gh}$**

3. Sunlight that passes through is absorbed by surface, heating it

4. Heated surface emits infrared radiation

5. Most of infrared radiation is trapped by atmosphere, keeping surface and atmosphere hot

Surface

# Temperature profiles for locked planet

$A =$  combined heating factor, curves for  $f=0.2 +$  local adv.

Wandel 2017

$$A = (1-a) H_{gh} F/F_E$$

$F/F_E$  stellar flux relative to Earth  
 $H_{gh}$  = Greenhouse heating factor

← Venus ( $A=30$ )

$A=10$   
 ← Mercury ( $A=6$ )

← Earth ( $A=1.2$ )

← Mars ( $A=0.3$ )

$A=0.1$

Prox b,  
 $H_{gh}$  1-10

Wandel 2017 (in rev)

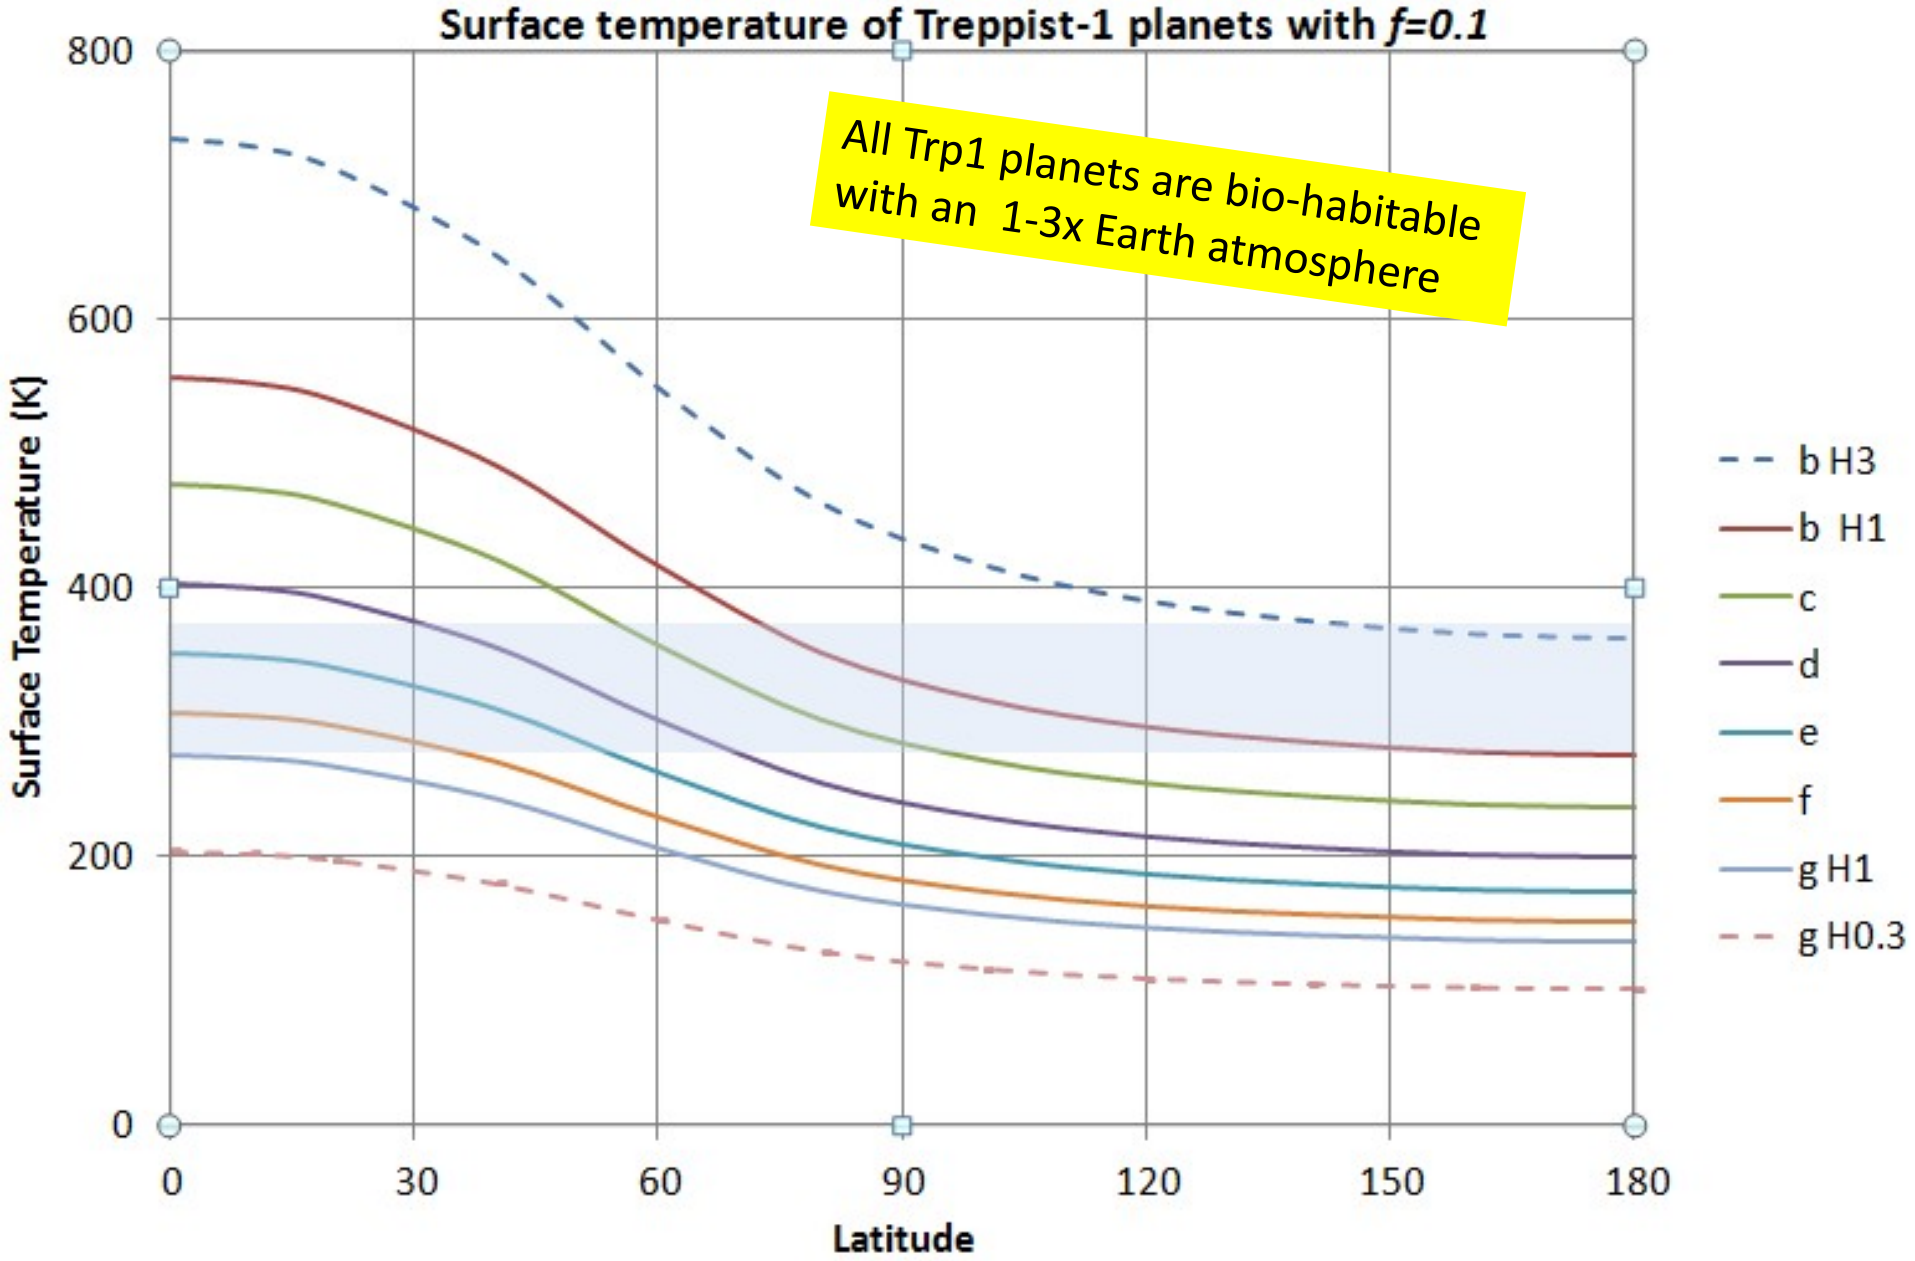

# Bio-habitability

Definition of the classical Habitable Zone:

surface temperatures allowing Liquid water

- Bio-HZ: surface temperatures allowing water *and* complex organic molecules ( $T=0\sim 130$  C)
- On at least part of the planetary surface
- Biohabitable temp. range for locked planets:
- $T$  (night side)  $< \sim 130$  C (bio habitability)
- $T$  (substellar point)  $> 0$  C (liquid water)

# Trappist-1 $\tau(\theta)$ profiles (with $A=1$ )

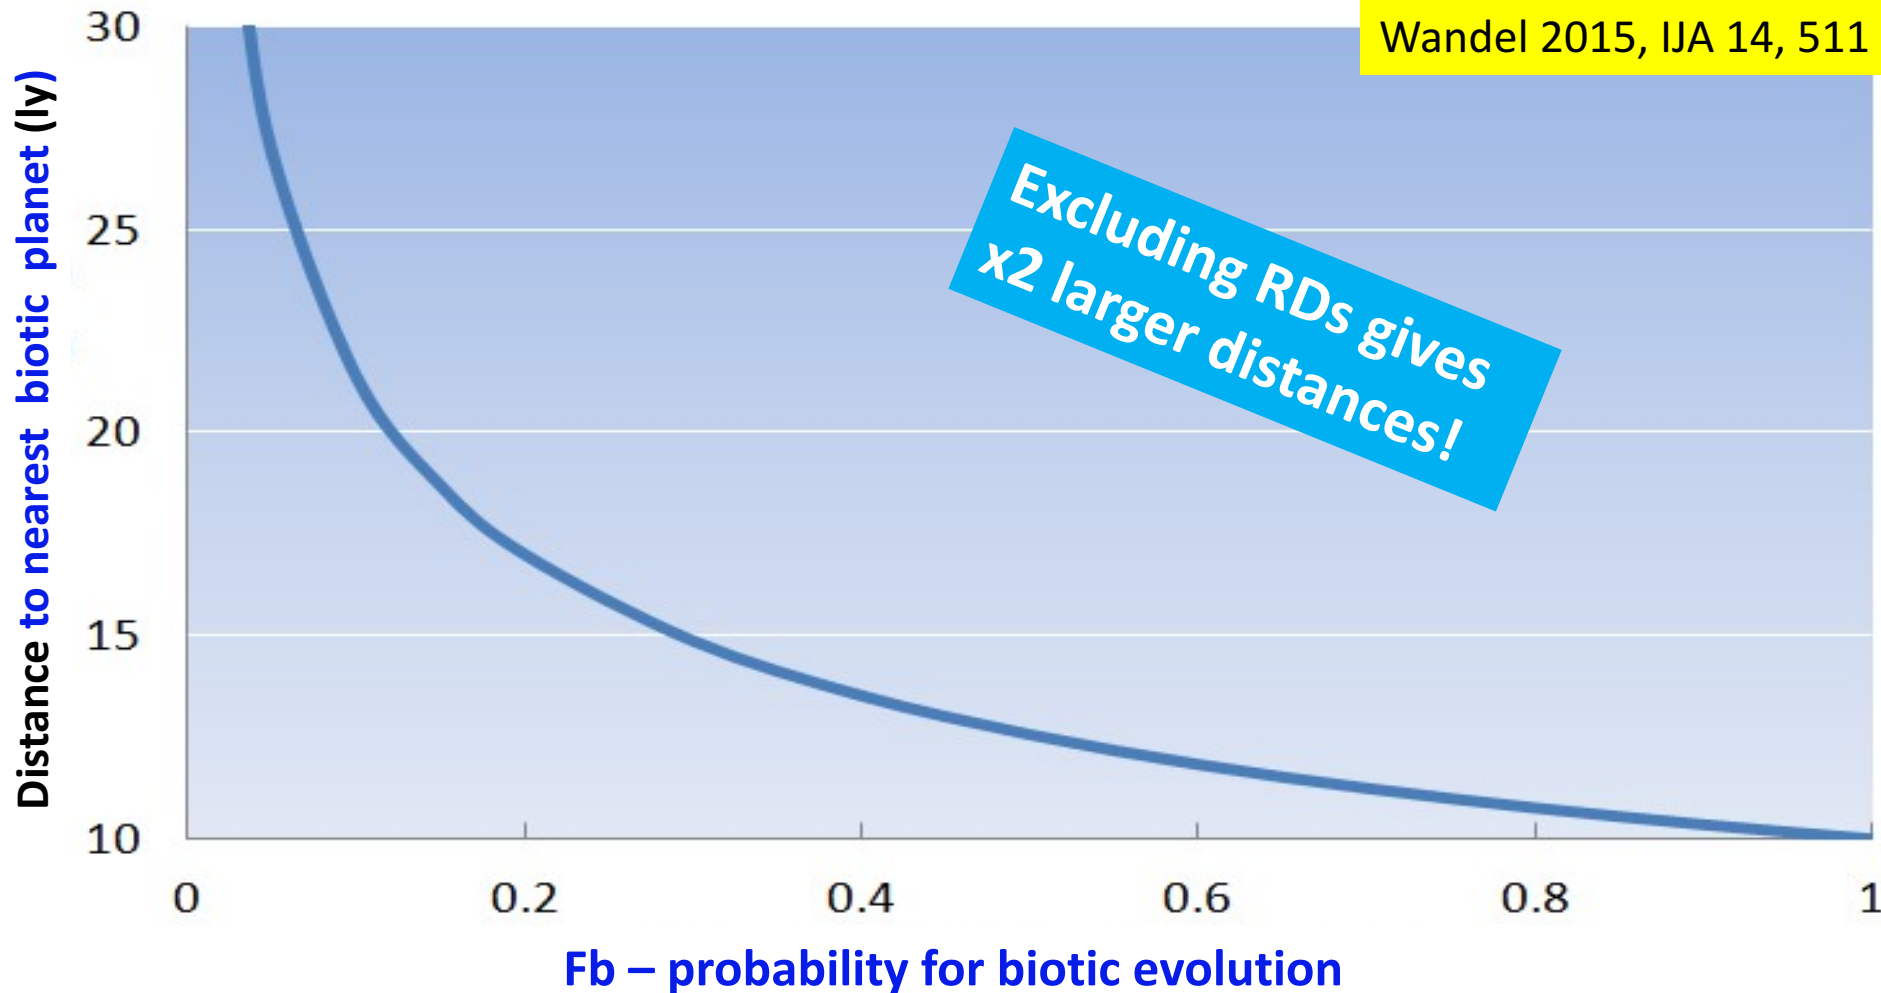

# Bio-habitable GH-range vs. planet distance (ie. flux)

# Bio-abundance: the distance to our nearest biotic neighbors

Wandel 2015, IJA 14, 511

# Bio-signatures

O<sub>3</sub> Ozone, produced by plants, algae

H<sub>2</sub>O Liquid water

Oxygen photosynthesis

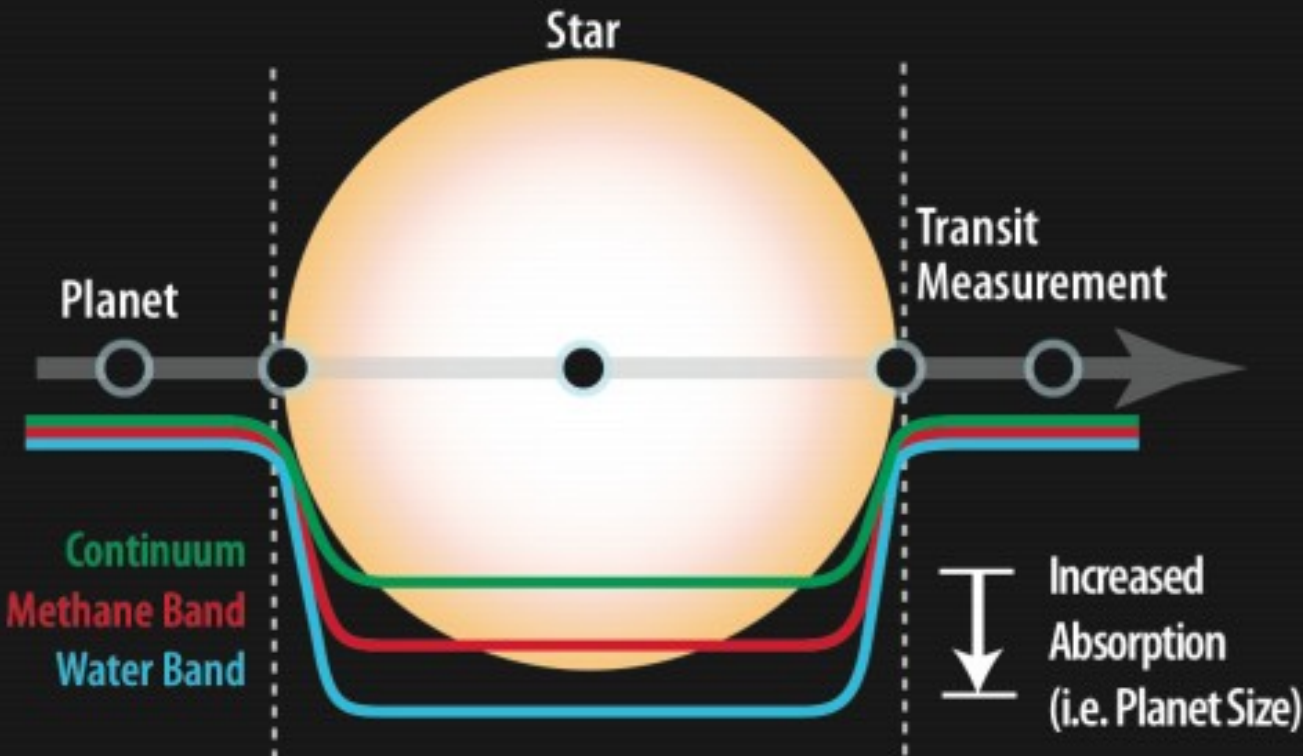

Water vapor

Spectral analyses

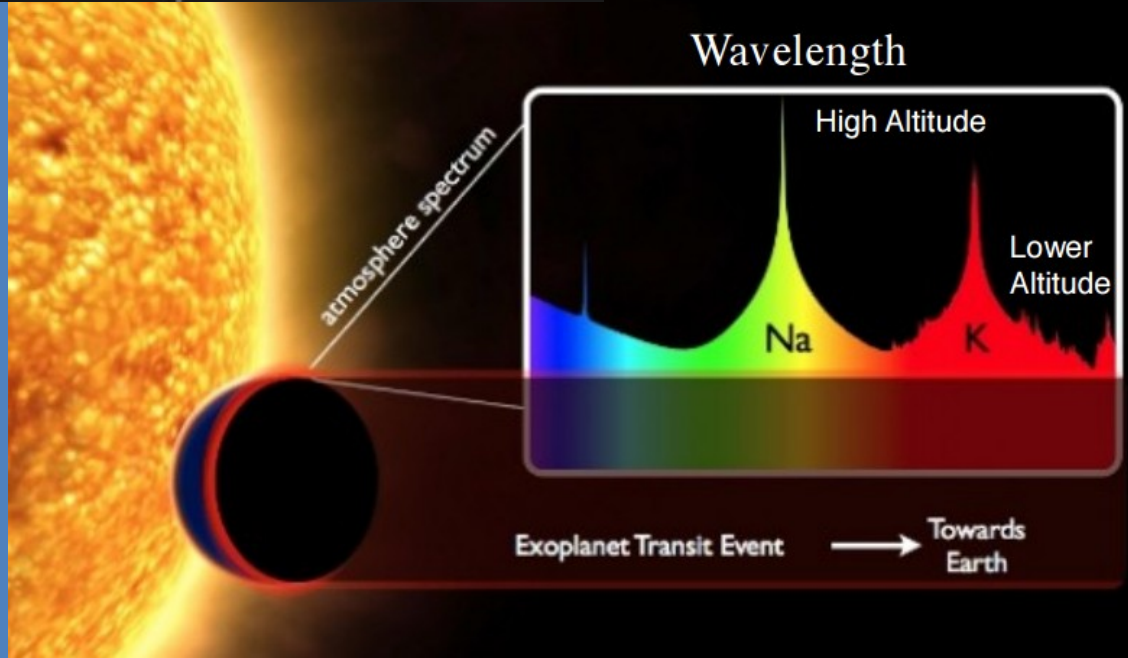

Methane produced by living organisms

Methane

# Bio-signatures for transiting planets

# Expected number. of transiting planets in HZ vs. detection range and biotic probability

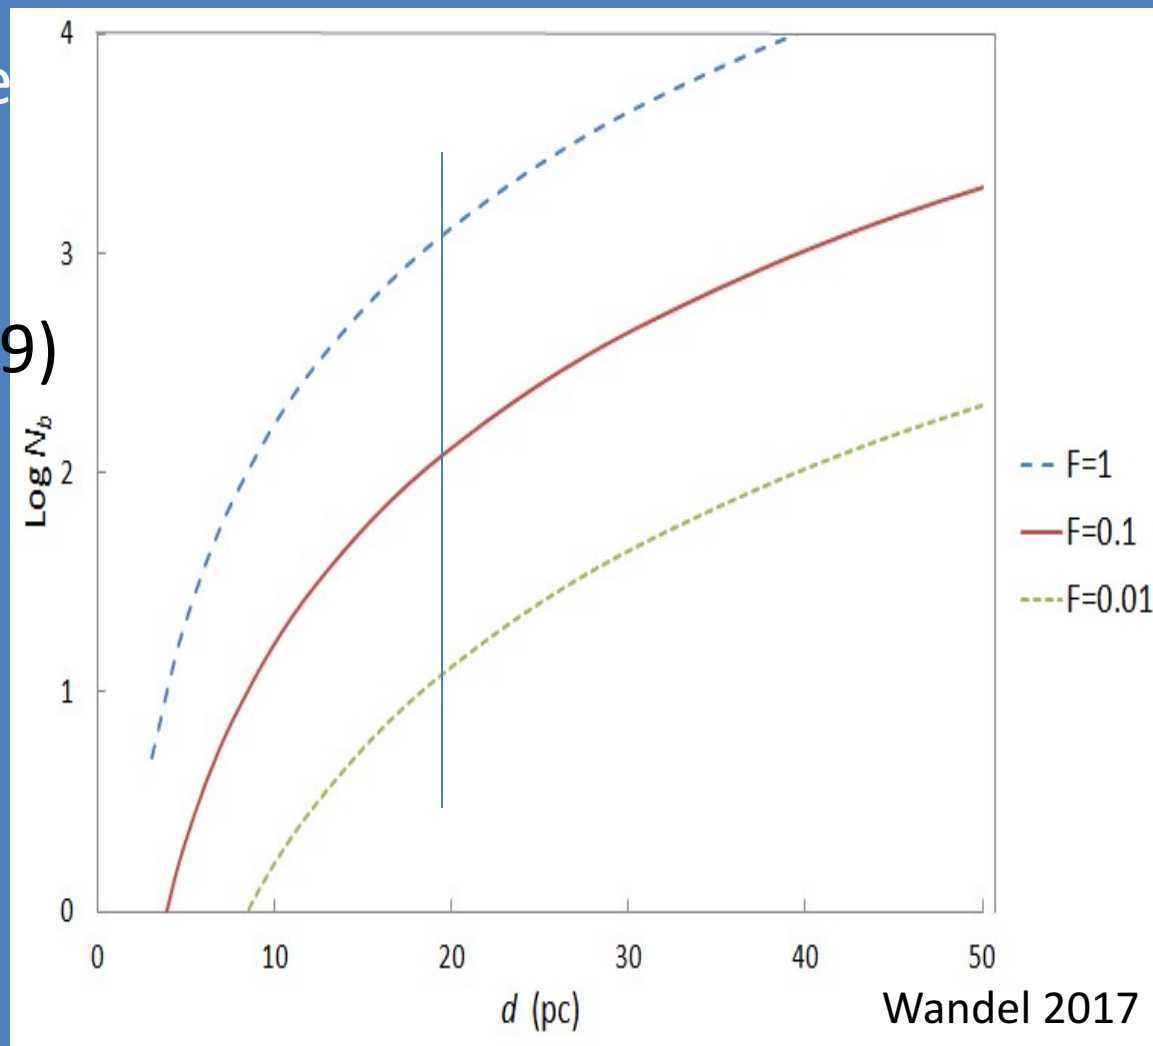

BioSig of transiting planets of M-dwarfs

Spectroscopy: JWST(2019)

Sample: TESS (2018)

$N$  depends on  $F_b$ -  
the **biotic probability**

and vice versa:  $N \rightarrow F_b$

# Conclusions

- Habitable Zone planets of red dwarf stars (RDP) may actually have conditions suitable to life
- Liquid water could exist on RDPs for a wide range of atmospheric properties (heating, redistribution)
- conditions on RDPs may be suitable for earthlike organic chemistry and life
- JWST may be able to detect bio-signatures for dozens of nearby transiting RDPs
- We may be able to find the abundance of biotic planets → estimate probability of life
