ABSTRACT

The process of editing a large atlas of charts is presented. The different steps include the extraction processes of the interesting information out of the GSC and DSS CD-ROMs, the elimination of noise, the technical aspects to produce the different charts (Parts D and G) and the difficulties linked to the number and the size of the files produced.

Key words: star charts; \LaTeX.

1. INTRODUCTION

A significant number of the stars measured by the Hipparcos satellite are uneasy to identify. They represent one tenth of the sample of about 120 thousand stars. To ensure a correct identification and to help people making additional measurements of these stars, an atlas of identification charts has been prepared.

The original idea (Mégevand 1991), used for the Hipparcos Input Catalogue Annex 2 (Grenon et al. 1992) was to prepare the charts with the Guide Star Catalog "GSC" (Lasker et al. 1990). In some situations however, it was impossible to get a correct chart from the GSC, the field around the star being too crowded, polluted by interstellar matter, having a background gradient due to a neighbouring bright star, and the like.

The atlas is therefore set in two parts, drawn with very different methods, according to the presence of the star in the GSC, and depending on the topography and content of the field:

\textbf{G part:} the main part is composed of 10877 charts drawn from the data of the GSC.

\textbf{D part:} for those more cumbersome situations, a bitmap image has been extracted from the Digitized Sky Survey 'DSS' (Djorgovski et al. 1992). This part represents 776 charts.

2. THE EDITORIAL PROCESS

The editorial process included the following steps, which are detailed in the following sections:

1. data extraction from the GSC and DSS CD-ROMs, putting for each field the relevant information in individual \LaTeX macro files for the G part and individual images for the D part;

2. single chart building using \LaTeX for the G part and adding an adequate PostScript header for the D part;

3. page composition made with \LaTeX, assembling 35 charts for the G part or 24 charts for the D part, with appropriate headers, footers, and scales.

3. PROCESSING OF THE G PART DATA

The GSC catalog used is version 1.1. It is distributed on two CD-ROMs, and contains data for nearly 19 million objects brighter than sixteenth magnitude, of which more than 15 million are stars.

The catalog is divided into 7.5 degrees declination zones. These zones are then subdivided into regions bounded by small circle segments of right ascension and great circles segments of declination. This allows to keep an about constant amount of data in each region.

The data for each chart is extracted from the CD-ROMs by a Fortran program which creates a data file containing the coordinates and magnitude of the field stars, as well as the HIP number, the magnitude, the Hipparcos corrected coordinates and the filter of the plate used for the central star. A cursor made by two horizontal line segments is added. These data are embedded in \LaTeX\ macros (see Figure 2), for later processing.

An iterative process is then run to correct the shape of the cursor, in case it overlaps another object. The editing process then double loops through pages and single charts to draw individual pictures and assemble them in the atlas. The process is detailed in Section 5. The entire process has been reprocessed by a slightly modified program to produce the individual PostScript files included in the Hipparcos ASCII CD-ROMs (Volume 17 of ESA [1997]).

4. PROCESSING OF THE D PART DATA

The DSS is distributed as two sets of 61 and 40 CD-ROMs, equal to 600 GB of data. Part I is digitized from the SERC Southern Sky Survey and the SERC J Equatorial extension. They are mainly IIIaJ plates, with the exception of some V-band plates. Part II (northern sky) is digitized from the 683 E plates from the 1950-55 epoch Palomar sky survey.

These 600 GB are compressed by a factor ten using a H-transform wavelet technique. To be able to process these data efficiently, they were decompressed and the original 16 bits/pixel encoding was replaced by a 4 bits/pixel one. This was achieved without a significant loss of quality. Then the files were recompressed. After that, all the data fit on a single 9 GB disk.
The extraction process uses the original PostScript function, slightly modified to access these data. The extraction process involves clipping and rotation to ensure homogeneous charts. Each chart is extracted into an individual bitmap image and a companion file containing the data needed to label the charts.

A PostScript header (see Figure 4) is added to each chart before the bitmap is rotated and clipped. This header includes a small circle representing the Hipparcos star's position, as measured by the instrument.

The editing process is similar to the G part, using an LATEX program to draw the individual charts by putting the useful information and a convenient cross-hair cursor around the Hipparcos star, then looping through the charts to set the pages (see Section 5).

One should note that the high proper motion stars are not in the plate position anymore, as indicated by the distance between the small circle cursor and the cross-hair cursor (see third chart of the last row in Figure 8).

The complete PostScript file for the atlases contains around 300 files, corresponding to approximately 1 GB of data. The complete PostScript file for the DSS charts is larger than 100 MB.
