ESA Webb Telescope @ESA_Webb
Astronomers using Webb have found the smallest free-floating brown dwarf so far. 🌌

Brown dwarfs are often called 'failed stars' – although they form like stars, they never gain enough mass to begin nuclear fusion. 🌌🔭

**What's the smallest a star can be?
Webb has brought astronomers closer
to the answer**

Astronomers may have found the smallest 'failed star' yet discovered.

Astronomy Picture of the Day

Discussion: Each day a different image or photograph of our fascinating universe is featured, along with a brief explanation written by a professional astronomer.

2024 January 13

The initial mass of a star determines its evolutionary path, but what dictates its initial mass?

Stars are fundamental components of our visible universe:

- Host planetary systems
- Building blocks of galaxies
- Source of chemical elements
- Progenitors of supernovae and black holes

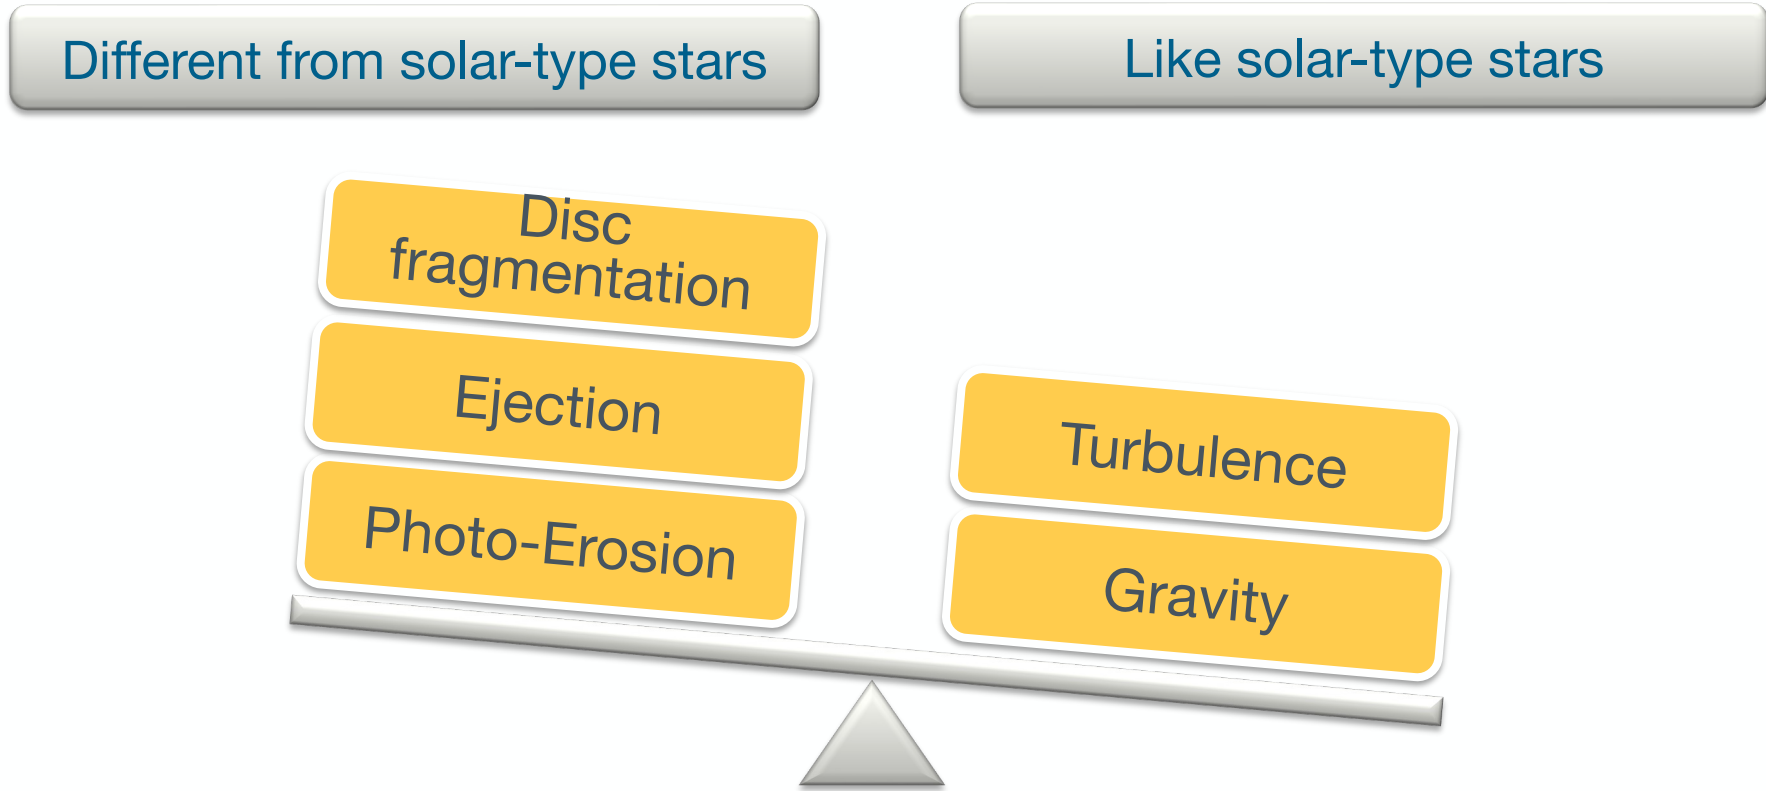

The Initial Mass Function, Bastian N, et al. 2010, AR, 48:339-89

Brown dwarfs, lacking the mass for stable hydrogen fusion and extending down to few Jupiters in mass, prompt the question: How do these objects form?

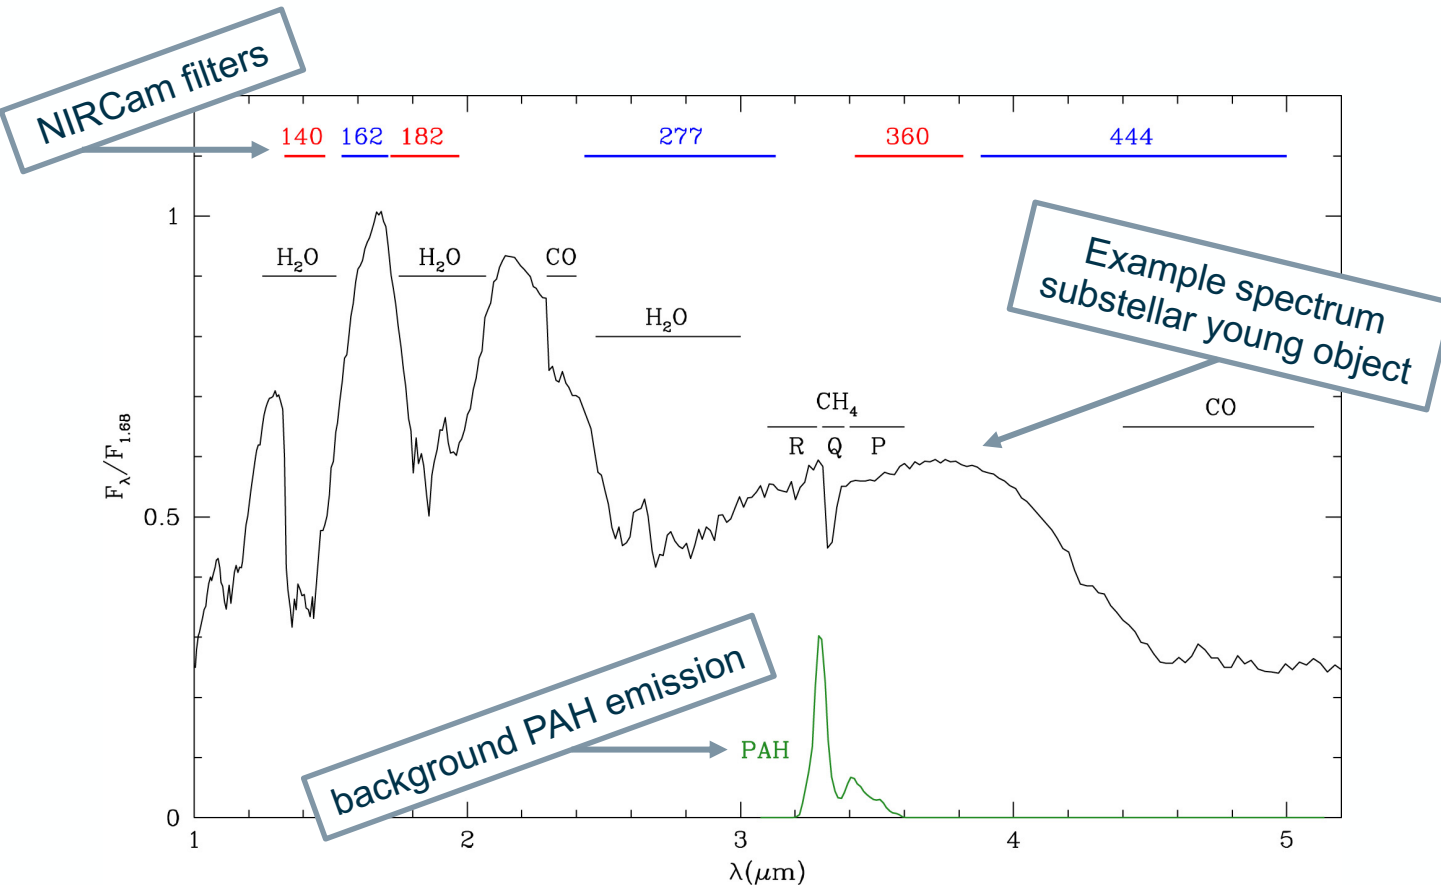

Relevance of mass function studies in the low-mass regime:

- Constrain the stellar and planet formation process
- Probe the universality and continuity of the mass function
- Drive census of these objects

Design of the observing program with JWST/NIRCam

- Based on known-spectra of brown-dwarfs, select best photometry filters to uncover new low-mass objects
- Design a mosaic pattern centred on the cluster IC 348 (distance~400 pc, age~3 Myr)

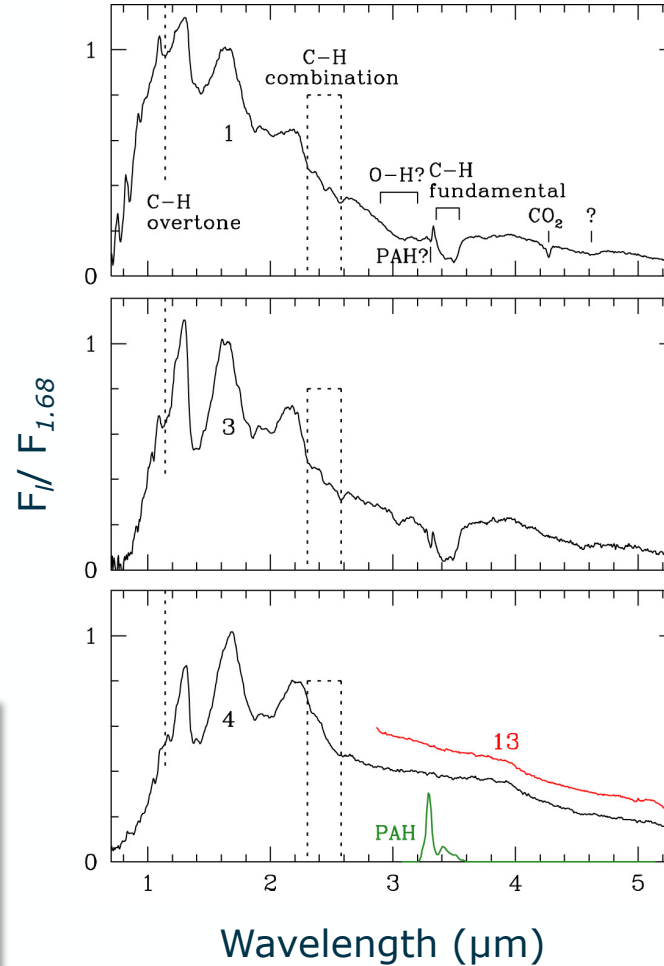

Uncovering the most promising candidate brown-dwarfs

- Observations:
28-August-2022
- Use the objects shape and photometric colours (differences in magnitudes from different filters) to select candidates
- Selected 4 high-priority targets and 5 complementary ones for spectroscopic follow-up

Using JWST/NIRSpec to study brown dwarf candidates

➤ Observations:
03-February-2023
(4.5 hours)

➤ Discarded 5 sources:

- Reddened field dwarfs in the background
- 1 field star or galaxy

➤ Confirmed 3 new members:

- Comparison between estimated luminosity to evolutionary models result in temperatures of 1100-1800K and 3-8MJup

- Source 3 is a contender for the least massive free-floating brown dwarf directly imaged to date

- 2 sources show a spectral signature of an unidentified hydrocarbon
- First time this molecule is detected in the atmosphere of an object outside our solar system
- Same infrared signature was detected by Cassini mission in the atmospheres of Saturn and its moon Titan, and modelled in terms of methane and other hydrocarbons, with a large component of the absorption still due to an unidentified aliphatic hydrocarbon
- One possibility is that these newly found objects inhabit a regime of physical properties that is previously unexplored (e.g., low temperature, low surface gravity, and thinning clouds)

Reference: Luhman, K., Alves de Oliveira, C. et al. 2024, AJ 167,19L <https://doi.org/10.3847/1538-3881/ad00b7>

- Planned observations in 2024 of these objects with higher resolution spectroscopy
- Proposals submitted to study these targets in the mid-IR, and also map a wider and deeper part of the cluster

Thank you
